1 Dovetailling enumeration and the π function

Let $(x)_i$ denothe the power of the *i*th prime factor in the decomposition of $x \in \omega$. Let φ_e an arbitrary partial computable function computed by program P_e . The Turing program P_e runs on discrete steps, and so we can conceive the following procedure:

- 1. Fix $n \leftarrow (x)_1, t \leftarrow (x)_2$.
- 2. If P_e halts in t steps from input n, halt and return 1.
- 3. Otherwise, set $x \leftarrow x + 1$ and go back to step (1).

This program halts if and only if P_e halts on some input, since eventually all possible inputs are considered. We use $\pi(x)$ to denote the partial computable function that performs the procedure above on program x. We observe that if $W_x \neq \emptyset$ then $\pi(x)$ always halts, meaning that $W_{\pi(x)} = \mathbb{N}$. On the contrary, if $W_x = \emptyset$ then $\pi(x)$ is undefined and $W_{\pi(x)} = \emptyset$.

Theorem 1. There is a partial computable function $\pi_k^c(x)$ that takes k arguments and halts with output c (independently of the arguments) if and only if $W_x \neq \emptyset$. Furthermore, if $W_x \neq \emptyset$, then $W_{\pi_k^c(x)} = \mathbb{N}$, and if $W_x = \emptyset$ then $W_{\pi_k^c(x)} = \emptyset$.

Proof. Trivial to derive from all of the above.

In general, if we use $\pi(x)$ to denote $\pi_1^1(x)$.

2 Index set theorems

Notation. Let \mathcal{F} be the set of partial computable functions. We use \bot_F to denote the partial computable function which is undefined on all input.

A set $A \subseteq \omega$ is an index set if for all $x, y \in \omega$,

$$x \in A \land \varphi_x = \varphi_y \Rightarrow y \in A$$

In other words, a set is an index set if all elements in the set index the same partial computable function.

Would it not be better to set $\varphi_x \simeq \varphi_y$? Think about this.

Trivially, ω and \emptyset are index sets.

Theorem 2 (Index set theorem). If A is a non-trivial index set, then either $K \leq_1 A$ or $K \leq_1 \overline{A}$. Furthermore, if $\bot_{\mathscr{F}} \in \overline{A}$ then $K \leq_1 A$, and vice-versa.

Proof. Assume the index of $\bot_{\mathscr{F}}$ is in A and take $y \in \overline{A}$. Define

$$\phi(u,v) = \begin{cases} \varphi_y(v) & u \in K \\ \bot & c.c. \end{cases}$$

The function above is computable. The S_n^m theorem ensures there is a total, one-to-one function f s.t. $\varphi_{f(u)}(v) = \phi(u, v)$.

If $u \in K$, then $\varphi_{f(u)} = \varphi_y$, meaning that $f(u) \in \overline{A}$. If $u \notin K$, then f(u) is the index of $\bot_{\mathscr{F}}$, which is in A.

$$\therefore K \leq_1 \overline{A}.$$

Theorem 3 (Rice's theorem). Let $\mathscr C$ any class of partial computable functions. Then $A = \{n : \varphi_n \in \mathscr C\}$ is not computable except in the trivial cases.

Proof. Assume the class $\mathscr C$ is non-trivial, meaning that $A = \{n : \varphi_n \in \mathscr C\}$ is neither ω nor \emptyset . Then $K \leq_1 A$ or $K \leq_1 \overline{A}$ by virtue of the index set theorem. Either case, A is not decidable.

2.1 Some interesting sets

The set of programs which halt with themselves as input (K), and the set of pairs (x, y) such that P_x halts on input y (K_0) , are not index sets. Index sets of interest are:

1. K_1 , the set of programs that halt on some input:

$$K_1:=\{x:W_x\neq\emptyset\}=\{x:\varphi_x=\bot_{\mathcal{F}}\}$$

2. Fin, the set of programs that halt for a finite number of inputs.

$$Fin := \{x : W_x \text{ is finite}\}\$$

- 3. The complement of *Fin*, termed *Inf*.
- 4. \mathcal{T} , the set of total computable functions.

- 5. $Con \subseteq \mathcal{T}$, the set of constant and total functions.
- 6. Cof, the set of programs that halt on a cofinite number of input.
- 7. *Rec*, the set of computable (recursive) programs.
- 8. Ext, the set of programs that can be extended to total computable functions.

An interesting factt is that $K \equiv_1 K_0 \equiv_1 K_1$. We already know that $K \leq_1 K_1$, because K_1 is a non-trivial index set, so let us observe the remaining relations.

 $(1: K_1 \le K)$ This is intuitively clear, since deciding whether a program halts with itself as input would suffice to decide whether it halts at all.

Recall that

$$W_{\pi(x)} = \begin{cases} \mathbb{N} & x \in K_1 \\ \emptyset & x \notin K_1 \end{cases}$$

This entails that if $x \in K_1$, then $\pi(x) \in W_{\pi(x)}$, which means that $\pi(x) \in K$. If $x \notin K_1$, clearly $\pi(x) \notin W_{\pi(x)}$, since said domain is the empty set, and $\pi(x) \notin K$.

 $(2: K_0 \le K)$ Observe that $x \in K \iff (x, x) \in K_0$. Define

$$\psi(x, y, z) = \begin{cases} \varphi_y(x) & (x, y) \in K_0 \\ \bot & c.c. \end{cases}$$

It is computable and therefore there is an index e s.t. $\psi(x, y, z) = \varphi_e(x, y, z)$. By virtue of the S_n^m theorem, there is a computable and one-to-one function f s.t. $\varphi_{f(e,x,y)}(z) = \varphi_e(x,y,z)$. Fix e and let g(x,y) = f(e,x,y).

Assume $(x, y) \in K_0$. Then $\varphi_{g(x,y)}(z)$ halts for all z. In particular, it halts for $\varphi_{g(x,y)}(g(x,y))$. This entails $g(x,y) \in K$.

Similarly, assume $(x, y) \notin K_0$. Then $\varphi_{g(x,y)}(z)$ halts for no input at all, i.e. $W_{g(x,y)} = \emptyset$. In particular, $g(x, y) \notin W_{g(x,y)}$, which means $g(x, y) \notin K$.

 $K_0 \leq K$.

All of this suffices to show $K_0 \equiv_1 K_1 \equiv_1 K$.

Definition 1. A computably enumerable set A is 1-complete if $W_e \leq_1 A$ for every computably enumerable set W_e .

Problem: Is K_0 1-complete? The answer is yes. Take W_e arbitrary and c.e. Then $x \in W_e$ if and only if $(x, e) \in K_0$. Thus suffices to show $W_e \le_1 K_0$.

2.2 Computable approximations to computations

We write $\varphi_{e,s}(x) = y$ if x, y, e < s and y is the output of $\varphi_e(x)$ in less than s steps of program P_e . If such a y exists we say $\varphi_{e,s}(x)$ converges. We define $W_{e,s} := \text{dom}(\varphi_{e,s})$.

Note that by def. fif $x \in W_{e,s}$ then x, e < s. Furthermore,

$$\varphi_e(x) = y \iff \exists s. \varphi_{e.s}(x) = y$$

Theorem 4. The set $\{(e, x, s) : \varphi_{e,s}(x) \downarrow \}$ is computable, as is the set $W_{e,s}$.
